Project Part 2 - 3D Scenes and Models

Q1 Updated Game Design Document

5 Points

Update the README file with the following sections, mirroring sections added in Checkpoint 1-2. For all future submissions, you will be repeating these steps so there won't be further examples or templates.

1. In your **Development Plan** section, strike-through tasks you have completed. For tasks you were unable to complete, provide a written justification for why the task wasn't completed for this submission. Add any major items you completed that you didn't plan for to the **Additions** subsubsection. Add a subsubsection to the development plan titled **Project Part 3: Visual Effects** and sketch out your plan for what you will implement involving textbook Chapters 11, 12, and 13.
2. In your **Development** section, add a subsection titled **Project Part 2: 3D Scenes and Models** and describe the elements you have added to your game for this submission with screen captures, videos, and/or other visuals. Cite and link to any assets (e.g. 3D models, textures, sounds, etc.) you are using.
3. Add a section at the bottom of your README titled **Instructions for Testing the Project** and, using bullets, explain how to play your game. This includes what keybinds correspond to what actions, what scenes we should open to see different functionalities, and anything else we might need to know to play, test, and grade your assignment.

Additionally, we will be checking to see that you incorporate the feedback you received from course staff on your previous submissions.

Once your readme file is ready, commit and push your changes to your group repo and obtain a link to this specific commit. Then, submit this link below.

Q2 Project Progress Commit

5 Points

For this submission, you should be adding, at a minimum, the following elements presented in Chapters 3, 4, 9, and 10 of the Hands On Unity Beginner's Guide course text.

1. Create the **game-world** that makes the most sense for your game. If it is set outside, create a terrain using **Terrain tools**. If it is set indoors, create the setting using **ProBuilder or by importing 3D models**.
2. Find and import **3D models** for your game elements. These do not have to be final versions, but they should be replacing your primitive placeholders. We are not expecting you to create your own assets. Use what you can find on the internet. On the course Canvas page, under the Resources link at the top, you may find a section on free assets with links to websites offering them. Retain links to 3D models found online and cite and link them in your game design document.
3. Implement **AI for enemy behavior** using the concepts discussed in Chapter 9.
4. Add **shaders, materials, and/or textures to your 3D models** as relevant to your game. Many 3D models you find on the internet will already come with these, but you can use the content of Chapter 10 to make your own as necessary. Retain links to shaders, materials, or textures found online and cite and link them in your game design document.
5. Continue implementing gameplay mechanics relevant to your game as explained in your game design document. We're expecting you to keep programming towards your goal project even when the textbook is focused on other topics.

If you are not sure about how one or more of the above aspects will work in your final game submission, it is acceptable to include elements to illustrate these concepts and to then adapt these elements and how they fit in your game in a later submission.

Use comments to **document your code**. We are primarily looking for you to add header comments to your scripts and headers in your public fields, to use self-documenting naming conventions,

and to comment any potentially confusing/ambiguous code. Include your team members' names in all source files.

To make grading easier, **copy the commit link in Q1 and paste it here as well**.

Q3 In-Class Presentation
0 Points

During class you will be presenting your game design document as well as demonstrating your current game implementation (refer to the course schedule for specific dates.) We will be grading you based on preparedness, ability to answer questions, and splitting up speaking between team members. Everyone should speak, and we would suggest that team members speak about the parts of the project they worked on implementing.

You will be given 15 minutes to present. Do **not** prepare other slides or materials outside of your game design document. You will use this document, as rendered on github, to present your work. Any elements you wish to present should be included there and/or in your current game version.

You are expected to attend both presentation days. We will be factoring your team's attendance and behavior during others' presentations into your grade.

The presentation grade will be assigned in the Individual Assessment.
